3.3. Odometry-based motion model

Odometry can be defined as the sum of wheel encoder pulses (see Fig. 1) to compute the robot pose. In this way, most robot bases/platforms provide some form of *odometry information*, a measurement of how much the robot has moved in reality. It is fun to know that cdometry comes from the Greek words ὁδός [odos] (route) and μέτρον [metron] (measurement), which mean *measurement of the route*.

Fig. 1: Example of a wheel encoder used to sum pulses and compute the robot pose.

Such information is yielded by the firmware of the robotic base, which computes it at very high rate (*e.g.* at 100Hz) considering constant linear v_t and angular w_t velocities. Concretely, if we know the total number of markers n_{total} (empty holes in the mask) the encoder has, the angle that the wheel turns per marker can be computed as:

$$\alpha = \frac{2\pi}{n_{total}} \text{ (radians)}$$

This angle increment is detected each time a pulse occurs. Then, in a given time interval Δt, the total angle rotated by the wheel given the number of pulses detected n_t is:

$$\Delta \beta_t = n_t \cdot \alpha \text{ (radians)}$$

This way, the angular velocity ω of the wheel can be computed as:

$$\omega \simeq \frac{\Delta \beta_t}{\Delta t} \text{ (radians/seconds)}$$

Note that this angular is speed is different from the one w.r.t. the ICR. Since we are considering a differential drive locomotion system, the pose increment can be retrieved as:

$$\Delta p = \begin{bmatrix} \Delta x \\ \Delta y \\ \Delta \theta \end{bmatrix} = \begin{bmatrix} \frac{v_p}{w} sin(w\Delta t) \\ \frac{v_p}{w}[1 - cos(w\Delta t)] \\ w\Delta t \end{bmatrix}$$

being $w = \frac{v_r - v_l}{l}$ the angular velocity of the robot w.r.t. the ICR (with l the distance between the wheels), v_r and v_l the linear velocities of the right and left wheels respectly, that can be computed from the previously obtained angular velocities ω_r and ω_l with $v = r \cdot \omega$ (r stands for the wheel radius), and v_p the linear velocity at the robot-axis midpoint that can be computed as $v_p = \frac{v_l + v_r}{2}$.

As commented, the firmware of the robotic base computes these pose increments at a very high rate, and makes it available to the robot at lower rate (*e.g.* 10Hz) using a tool that we already know: the composition of poses:

Fig. 2: Example of composition of poses based on odometry.

Note that between the two odometry poses provided by the robotic base, there have been a series of pose increments computed by said firmware.

The **odometry motion model** consists of the utilization of such information that, although technically being a measurement rather than a control, will be treated as a control command to

simplify the modeling. Thus, the odometry commands take the form of:

$$u_t = f(odom_t, odom_{t-1}) = \begin{bmatrix} \Delta x \\ \Delta y \\ \Delta \theta \end{bmatrix}$$

being $odom_t$ and $odom_{t-1}$ measurements taken as control and computed from the odometry at time instants t and $t-1$.

We will implement this motion model in two different forms:

- Analytical form, where the motion command is an increment: $u_t = [\Delta x_t, \Delta y_t, \Delta \theta_t]^T$
- Sample form, where it is a combination of a rotation, motion in straight line, and rotation: $u_t = [\theta_1, d, \theta_2]^T$

In this way, the utilization of the odometry motion model is more suitable to keep track and estimate the robot pose in contrast to the *velocity model*: it is more accurate, but measurements are available only after the motion is completed.

```python
In [ ]: %matplotlib widget

# IMPORTS
import numpy as np
from numpy import random
import matplotlib.pyplot as plt
from scipy import stats
from IPython.display import display, clear_output
import time

import sys
sys.path.append("..")
from utils.DrawRobot import DrawRobot
from utils.PlotEllipse import PlotEllipse
from utils.pause import pause
from utils.Jacobians import J1, J2
from utils.tcomp import tcomp
```

OPTIONAL

Let's compute an odometry pose as the robot base firmware does! Implement a method that, given a number of pulses detected in both wheels, computes the angles that the wheels turned and the resultant angular velocities. Then, implement a second one that retrieves the robot pose increment from those velocities, given a time increment Δt. Finally, given a vector of pulses detected from each wheel, compute their respective pose increments, and provide the final odometry pose.

END OF OPTIONAL PART

3.3.1 Analytic form

Just as we did in chapter 3.1, the analytic form of the odometry motion model uses the composition of poses to model the robot's movement, providing only a notion of how much the pose has changed, not how did it get there.

As with the *velocity model*, the odometry one uses a gaussian distribution to represent the **robot pose**, so $x_t \sim (\overline{x}_t, \Sigma_{x_t})$, being its mean and covariance computed as:

- **Mean:**

$$\overline{x}_t = g(\overline{x}_{t-1}, \overline{u}_t) = \overline{x}_{t-1} \oplus \overline{u}_t$$

where $u_t = [\Delta x_t, \Delta y_t, \Delta \theta_t]^T$, so:

$$g(\overline{x}_{t-1}, \overline{u}_t) = \begin{bmatrix} x_1 + \Delta x \cos \theta_1 - \Delta y \sin \theta_1 \\ y_1 + \Delta x \sin \theta_1 - \Delta y \cos \theta_1 \\ \theta_1 + \Delta \theta \end{bmatrix}$$

- **Covariance:** $$\Sigma_{x_t} = \frac{\partial g}{\partial x_{t-1}} \cdot \Sigma_{x_{t-1}} \cdot {\frac{\partial g}{\partial x_{t-1}}}^T$$

- \frac{\partial g}{\partial u_{t}} \cdot \Sigma_{u_t} \cdot {\frac{\partial g}{\partial u_{t}}}^T \[10pt]

$where$\partial g/\partial x_{t-1}and\partial g/\partial u_t$are the jacob

$x_{t-1}$and the c

\frac{\partial g}{\partial x_{k-1}}

$$\begin{bmatrix} 1 & 0 & -\Delta x_k \sin \theta_{k-1} - \Delta y_k \cos \theta_{k-1} \\ 0 & 1 & \Delta x_k \cos \theta_{k-1} - \Delta y_k \sin \theta_{k-1} \\ 0 & 0 & 1 \end{bmatrix}$$

, , , , , , , , , , , , \frac{\partial g}{\partial u_k}

$$\begin{bmatrix} \cos \theta_{k-1} & -\sin \theta_{k-1} & 0 \\ \sin \theta_{k-1} & \cos \theta_{k-1} & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

$

$and the covariance matrix of this movement(Σ_{u_t})is defined as seen below. Typically, it is

$*$ $(travelled distance and turned angle) could be used to parametrize it.$

$

\Sigma_{u_t} =

$$
\begin{bmatrix}
\sigma^2_{\Delta x} & 0 & 0 \\
0 & \sigma^2_{\Delta y} & 0 \\
0 & 0 & \sigma^2_{\Delta \theta}
\end{bmatrix}
$$

$$

ASSIGNMENT 1: The model in action

Similarly to the assignment 3.1, we'll move a robot along a 8-by-8 square (in meters), in increments of 2m. In this case you have to complete:

- The `step()` method to compute:
    - the new expected pose (`self.pose`),
    - the new true pose x_t (ground-truth `self.true_pose`) after adding some noise using `stats.multivariate_normal.rvs()` to the movement command u according to `Q` (which represents Σ_{u_t}),
    - and to update the uncertainty about the robot position in `self.P` (covariance matrix Σ_{x_t}). Note that the methods `J1()` and `J2()` already implement $\partial g/\partial x_{t-1}$ and $\partial g/\partial u_t$ for you, you just have to call them with the right input parameters.
- The `draw()` method to plot:
    - the uncertainty of the pose as an ellipse centered at the expected pose, and
    - the true position (ground-truth).

We are going to consider the following motion covariance matrix (it is already coded for you):

$$
\Sigma_{u_t} =
\begin{bmatrix}
0.04 & 0 & 0 \\
0 & 0.04 & 0 \\
0 & 0 & 0.01
\end{bmatrix}
$$

Example

Fig. 2: Movement of a robot using odometry commands.
Representing the expected pose (in red), the true pose (as dots)
and the confidence ellipse.

```python
In [ ]: class Robot():
    """ Simulation of a robot base

        Attrs:
            pose: Expected pose of the robot
            P: Covariance of the current pose
            true_pose: Real pose of the robot(affected by noise)
            Q: Covariance of the movement
    """
    def __init__(self, x, P, Q):
        self.pose = x
        self.P = P
        self.true_pose = self.pose
        self.Q = Q

    def step(self, u):
        # TODO Update expected pose
```

```python
        prev_pose = self.pose
        self.pose = tcomp(prev_pose, u)

        # TODO Generate true pose
        noisy_u = np.vstack(np.vstack(stats.multivariate_normal.rvs(u.flatten(),self.Q))
        self.true_pose = tcomp(self.true_pose, noisy_u)

        # TODO Update covariance
        JacF_x = J1(prev_pose,u)
        JacF_u = J2(prev_pose, u)

        self.P = (
            (JacF_x@self.P@np.transpose(JacF_x))
            + (JacF_u@self.Q@np.transpose(JacF_u))
        )

    def draw(self, fig, ax):
        DrawRobot(fig, ax, self.pose)
        el = PlotEllipse(fig, ax, self.pose, self.P)
        ax.plot(self.true_pose[0], self.true_pose[1], 'o', color=el[0].get_color())
```

You can use the following demo to **try your new `Robot()` class**.

```python
In [ ]:  def demo_odometry_commands_analytical(robot):
            # MATPLOTLIB
            fig, ax = plt.subplots()
            ax.set_xlim([-3, 11])
            ax.set_ylim([-3, 11])
            plt.ion()
            plt.grid()
            plt.fill([2, 2, 6, 6],[2, 6, 6, 2],facecolor='lightgray', edgecolor='gray', linewidth
            plt.tight_layout()
            fig.canvas.draw()

            # MOVEMENT PARAMETERS
            nSteps = 15
            ang = -np.pi/2 # angle to turn in corners
            u = np.vstack((2., 0., 0.))

            # MAIN LOOP
            for i in range(nSteps):
                # change angle on corners
                if i % 4 == 3:
                    u[2, 0] = ang

                #Update positions
                robot.step(u)

                # Restore angle iff changed
                if i % 4 == 3:
                    u[2, 0] = 0

                # Draw every loop
                robot.draw(fig, ax)
                clear_output(wait=True)
                display(fig)
                time.sleep(0.3)

            plt.close()

In [ ]:  x = np.vstack([0., 0., np.pi/2]) # pose inicial

         # Probabilistic parameters
```
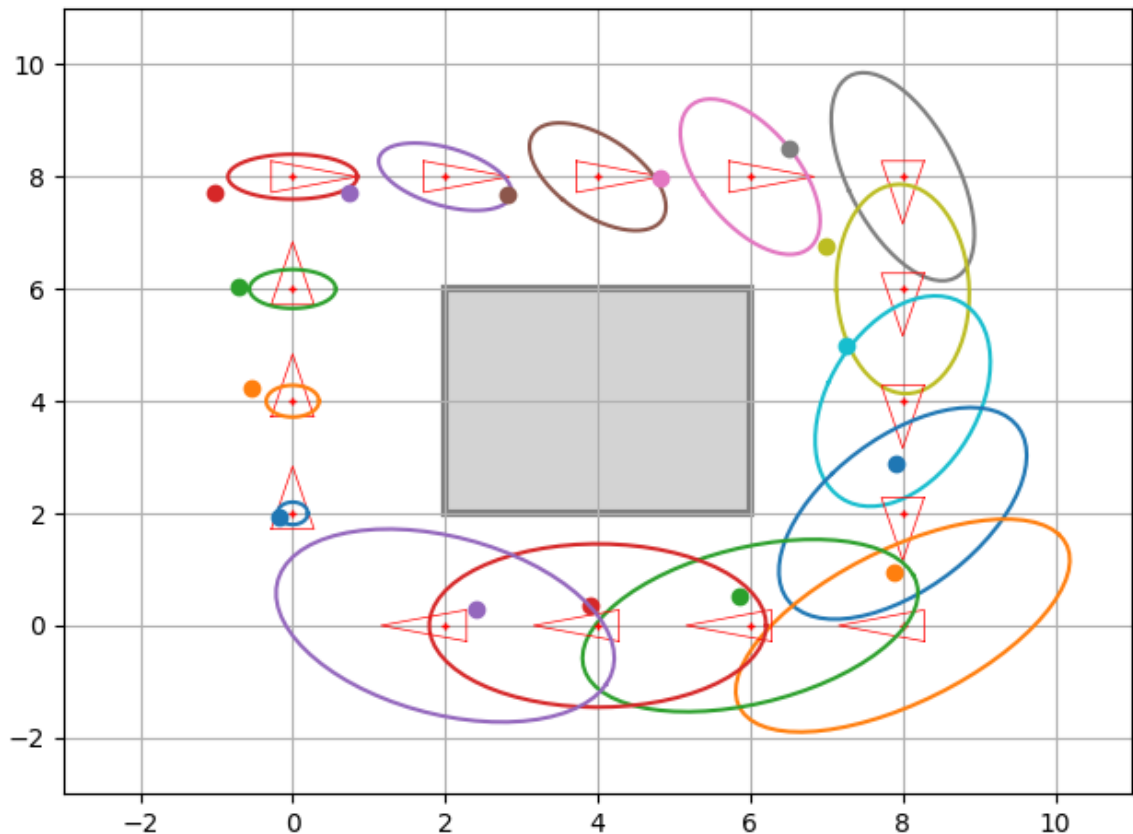

```
P = np.diag([0., 0., 0.])
Q = np.diag([0.04, 0.04, 0.01])

robot = Robot(x, P, Q)
demo_odometry_commands_analytical(robot)
```

Thinking about it (1)

Once you have completed this assignment regarding the analytical form of the odometry model, **answer the following questions**:

- Which is the difference between the $g(\cdot)$ function used here, and the one in the velocity model?

    El modelo de velocidad tiene en cuenta la velocidad lineal y angular del móvil como parámetros de entrada, en cambio el modelo basado en odometría tiene en cuenta la velocidad de cada rueda basadas en su posición

- How many parameters compound the motion command u_t in this model?

    Lo componen: Δxt, Δyt y $\Delta \theta t$ (3)

- Which is the role of the Jacobians $\partial g / \partial x_{t-1}$ and $\partial g / \partial u_t$?

    Se usa para modificar u y la pose previa al mismo sistema de referencia para trabajar con ellos

- What happens if you modify the covariance matrix Σ_{u_t} modeling the uncertainty in the motion command u_t? Try different values and discuss the results.

    Si aumentamos los valores Δxt o Δyt se aumentará la incertidumbre sobre el eje correspondiente, así como si se aumenta $\Delta \theta t$ aumenta la incertidumbre sobre la posición en cada giro. En general, se va cambiando su incertidumbre según modifiquemos sus parámetros.

3.3.2 Sample form

The analytical form used above, although useful for the probabilistic algorithms we will cover in this course, does not work well for sampling algorithms such as particle filters.

The reason being, if we generate random samples from the gaussian distributions as in the previous exercise, we will find some poses that are not feasible to the non-holonomic movement of a robot, i.e. they do not correspond to a velocity command (v, w) with noise.

The following *sample form* is a more realistic way to generate samples of the robot pose. In this case, the movement of the robot is modeled as a sequence of actions (see Fig 3):

1. **Turn** (θ_1): to face the destination point.
2. **Advance** (d): to arrive at the destination.
3. **Turn** (θ_2): to get to the desired angle.

Fig. 3: Movement of a robot using odometry commands in sampling form.

So this type of order is expressed as:

$$u_t = \begin{bmatrix} \theta_1 \\ d \\ \theta_2 \end{bmatrix}$$

It can easily be generated from odometry poses $[\hat{x}_t, \hat{y}_t, \hat{\theta}_t]^T$ and $[\hat{x}_{t-1}, \hat{y}_{t-1}, \hat{\theta}_{t-1}]^T$ given the following equations:

$$\theta_1 = atan2(\hat{y}_t - \hat{y}_{t-1}, \hat{x}_t - \hat{x}_{t-1}) - \hat{\theta}_{t-1} \tag{1}$$
$$d = \sqrt{(\hat{y}_t - \hat{y}_{t-1})^2 + (\hat{x}_t - \hat{x}_{t-1})^2}$$
$$\theta_2 = \hat{\theta}_t - \hat{\theta}_{t-1} - \theta_1$$

Note: the hat ˆ indicates values in the robot's internal coordinate system, which may not match the world reference system.

ASSIGNMENT 2: Implementing the sampling form

Complete the following cells to experience the motion of a robot using the sampling form of the odometry model. For that:

1. Implement a function that, given the previously mentioned $[\hat{x}_t, \hat{y}_t, \hat{\theta}_t]^T$ and $[\hat{x}_{t-1}, \hat{y}_{t-1}, \hat{\theta}_{t-1}]^T$ generates an order $u_t = [\theta_1, d, \theta_2]^T$

```
In [ ]:  def generate_move(pose_now, pose_old):
             diff = pose_now - pose_old
             theta1 = np.arctan2(pose_now[1]-pose_old[1],pose_now[0]-pose_old[0]) -pose_old[2]
             d = np.sqrt((pose_now[1]-pose_old[1])**2 + (pose_now[0]-pose_old[0])**2)
             theta2 = pose_now[2]-pose_old[2]-theta1
             return np.vstack((theta1, d, theta2))
```

Try such function with the code cell below:

```
In [ ]:  generate_move(np.vstack([0., 0., 0.]), np.vstack([1., 1., np.pi/2]))
```

`array([[-3.92699082],`
`        [ 1.41421356],`
`        [ 2.35619449]])`

Expected output for the commented example:

```
array([[-3.92699082],
       [ 1.41421356],
       [ 2.35619449]])
```

2. Using the resulting control action $u_t = [\hat\theta_1, \hat{d}, \hat\theta_2]^T$ we can model its noise in the following way:

$$\theta_1 = \hat\theta_1 + \text{sample}\left(\alpha_0\hat\theta_1^2 + \alpha_1\hat{d}^2\right) \tag{2}$$

$$d = \hat{d} + \text{sample}\left(\alpha_2\hat{d}^2 + \alpha_3\left(\hat\theta_1^2 + \hat{d}^2\right)\right)$$

$$\theta_2 = \hat\theta_2 + \text{sample}\left(\alpha_0\hat\theta_2^2 + \alpha_1\hat{d}^2\right)$$

Where $sample(b)$ generates a random value from a distribution $N(0, b)$. The vector $\alpha = [\alpha_0, \ldots, \alpha_3]$ (`a` in the code), models the robot's intrinsic noise.

The pose of the robot at the end of the movement is computed as follows:

$$x_t = x_{t-1} + d\cos(\theta_{t-1} + \theta_1) \tag{3}$$

$$y_t = y_{t-1} + d\sin(\theta_{t-1} + \theta_1)$$

$$\theta_t = \theta_{t-1} + \theta_1 + \theta_2$$

Complete the `step()` and `draw()` methods to:

- Update the expected robot pose (`self.pose`) and generate new samples. The number of samples is set by `n_samples`, and `self.samples` is in charge of storing such samples. Each sample can be interpreted as one possible pose reached by the robot.
- Draw the true pose of the robot (without angle) as a cloud of particles (samples of possible points which the robot can be at). Play a bit with different values of `a` . To improve this visualization the robot will move in increments of 0.5 and we are going to plot the particles each 4 increments.

Example

Fig. 1: Movement of a robot using odometry commands in sampling form.
Representing the expected pose (in red) and the samples (as clouds of dots)

In [ ]:
```python
class SampledRobot(object):
    def __init__(self, mean, a, n_samples):
        self.pose = mean
        self.a = a
        self.samples = np.tile(mean, n_samples)

    def step(self, u):
        # TODO Update pose
        ang = self.pose[2, 0] + u[0, 0]
        self.pose[0, 0] += u[1, 0]*np.cos(ang)
        self.pose[1, 0] += u[1, 0]*np.sin(ang)
        self.pose[2, 0] = ang+u[2, 0]
```

```python
        # TODO Generate new samples
        sample = lambda b: stats.norm(loc=0, scale=b).rvs(size=self.samples.shape[1])

        u2 = u**2

        noisy_u = u + np.vstack((
            sample((self.a[0]*(u[0, 0])**2)+(self.a[1]*(u[1, 0])**2)),
            sample((self.a[2]*(u[1, 0])**2)+((self.a[3])**2+(u[1, 0])**2)),
            sample((self.a[0]*(u[2, 0])**2)+(self.a[1]*(u[1, 0])**2))
        ))

        # TODO Update particles (robots) poses
        ang = self.samples[2, :] + noisy_u[0, :]

        self.samples[0, :] +=noisy_u[1, 0]*np.cos(ang)
        self.samples[1, :] += noisy_u[1, 0]*np.sin(ang)
        self.samples[2, :] = ang+noisy_u[2, 0]

    def draw(self, fig, ax):
        DrawRobot(fig, ax, self.pose)
        ax.plot(self.samples[0, :], self.samples[1, :], '.')
```

Run the following demo to **test your code**:

```python
def demo_odometry_commands_sample(robot):
    # PARAMETERS
    inc = .5
    show_each = 4
    limit_iterations = 32

    # MATPLOTLIB
    fig, ax = plt.subplots()
    ax.set_xlim([-3, 11])
    ax.set_ylim([-3, 11])
    plt.ion()
    plt.grid()
    plt.tight_layout()

    # MAIN LOOP
    robot.draw(fig, ax)
    inc_pose = np.vstack((0., inc, 0.))

    for i in range(limit_iterations):
        if i == 16:
            inc_pose[0, 0] = inc
            inc_pose[1, 0] = 0
            inc_pose[2, 0] = -np.pi/2

        u = generate_move(robot.pose+inc_pose, robot.pose)

        robot.step(u)

        if i == 16:
            inc_pose[2, 0] = 0

        if i % show_each == show_each-1:
            robot.draw(fig, ax)
            clear_output(wait=True)
            display(fig)
            time.sleep(0.1)

    plt.close()
```
```
In [ ]:  # RUN
         n_particles = 100
         a = np.array([.07, .07, .03, .05])
         x = np.vstack((0., 0., np.pi/2))

         robot = SampledRobot(x, a, n_particles)
         demo_odometry_commands_sample(robot)
```

Thinking about it (2)

Now you are an expert in the sample form of the odometry motion model! **Answer the following questions**:

- Which is the effect of modifying the robot's intrinsic noise α (a in the code)?

  Según modifiquemos los valores de alfa haremos que la posición real robot se aleje más a la esperada o menos

- How many parameters compound the motion command u_t in this model?

  d ,θ_1 y θ_2 (3)

- After moving the robot a sufficient number of times, what shape does the distribution of samples take?

  Toma forma de campana
